

Our product is based on the current need to learn the English language and the way in which many people decide to undertake this journey, therefore, we decided to investigate how we could address this issue and we came up with the idea of creating an interactive voice tool based on artificial intelligence, which would help us to provide a service in which people get useful information about their learning and use of English through this AI. For which we need objectives that are concrete to the needs of the population to which we want to provide the service we develop and that we already know due to our research, these were to provide a satisfactory and useful experience for the user, therefore, we had to determine which AI model would be used for our project, and how it would be more feasible to distribute it, in the end we came up with the Open AI model for chatGPT and an Alexa skill.

Our product did not contain much design since it is a voice interface, so we dedicated ourselves to get the best result in the answers given by the AI we still decided to create certain basic graphics for logos and such, because we believed they fit, most of them are light and discrete, but say a lot about the purpose of the application, For our evaluations we decided to use usability tests, which gave us the guideline of how our application works in real life and gave us good step to further develop the application and have enough skills to have a better understanding of the real application of this application rather than in our vision alone.
